Wavelength-division multiplexing (WDM) is defined as a technology that multiplexes multiple optical carrier signals onto an optical fiber by using different wavelengths of laser light, enabling bidirectional ...

Overview Systems Coarse WDM Dense WDM Enhanced WDM Shortwave WDM Transceivers versus transponders See also A WDM system uses a multiplexer at the transmitter to join the several signals together and a demultiplexer at the receiver to split them apart. With the right type of fiber, it is possible to have a device that does both simultaneously and can function as an optical add-drop multiplexer. The optical filtering devices used have conventionally been etalons (stable solid-state single-frequency Fabry-Pérot interferometers in the form of ...
