

The electrodes in the distribution box suddenly reversed

An electric current from the gel box and electrodes is added to the gel, causing the DNA molecules to separate and leave bands in the gel. The gel is read by measuring how far the bands have traveled.

Some older GFCI receptacles would go faulty and produce a hot-ground-reverse reading in downstream receptacles. As I recall, it happens when you don't push the reset button all the way in ...

The power distribution box has two input terminals so that power can be continually supplied while a battery is swapped out. I am currently using Wago 221-415 connectors to distribute the power.

In summary, putting the lid of the agarose gel electrophoresis apparatus on "backwards" can result in incorrect migration of molecules, uneven distribution of heat, and safety concerns. It is important to ...

Participants explore theoretical and practical aspects of these topics. Some participants discuss the consequences of incorrectly hooking up electrodes in gel electrophoresis, noting that ...

Some RCD will trip if the polarity is wrong (i.e. L and N swapped) or if there is no CPC (earth) connection. Both faults are very serious so it needs to be identified and fixed urgently! You ...

if your dna is running in the wrong direction then you probably have the black and red electrode leads connected the wrong way round but in the picture you show it is running correctly so the ...

What would happen if the electrodes were points instead of lines? What other physical insights can be learned from this application of an electric field for biological analysis?

This article reports a rare case where multiple limb and chest leads were reversed due to the reversal of cables leading to a false diagnosis of myocardial ischemia.

The electrodes in the distribution box suddenly reversed
